#### Informed Search Algorithms

Chapter 4, Sections 1–2

# Best-first search

Idea: use an evaluation function for each node - estimate of "desirability"

⇒ Expand most desirable unexpanded node

#### Implementation:

fringe is a queue sorted in decreasing order of desirability

#### Special cases:

greedy search A\* search

Chapter 4, Sections 1–2 1

## Outline

 $\mathsf{A}^*$  search

♦ Heuristics

#### Review: Tree search

 $\begin{array}{l} \textbf{function Tree-Search}(\textit{problem}, \textit{fringe}) \ \textbf{returns} \ \textbf{a} \ \textbf{solution}, \ \textbf{or} \ \textbf{failure} \\ \textit{fringe} \leftarrow \text{INSERT}(\text{MAKE-NODE}(\text{INITIAL-STATE}[\textit{problem}]), \textit{fringe}) \end{array}$ loop do

if fringe is empty then return failure

 $node \leftarrow Remove-Front(fringe)$ 

if GOAL-TEST[problem] applied to STATE(node) succeeds return node fringe  $\leftarrow$  INSERTALL(EXPAND(node, problem), fringe)

A strategy is defined by picking the order of node expansion

#### Greedy search

Evaluation function h(n) (heuristic)

= estimate of cost from n to the closest goal

E.g.,  $h_{\mathrm{SLD}}(n) = \mathrm{straight}\text{-line}$  distance from n to Bucharest

Greedy search expands the node that **appears** to be closest to goal

### Properties of greedy search

Complete?? No-can get stuck in loops, e.g.,

 $\mathsf{lasi} \to \mathsf{Neamt} \to \mathsf{lasi} \to \mathsf{Neamt} \to$ 

Complete in finite space with repeated-state checking

<u>Time??</u>  $O(b^m)$ , but a good heuristic can give dramatic improvement

Space??

Chapter 4, Sections 1–2 13

#### $A^*$ search

Idea: avoid expanding paths that are already expensive

Evaluation function f(n) = g(n) + h(n)

 $g(n) = \mathsf{cost} \; \mathsf{so} \; \mathsf{far} \; \mathsf{to} \; \mathsf{reach} \; n$ 

 $h(n)={\it estimated cost\ to\ goal\ from\ }n$ 

 $f(n)={\it estimated}$  total cost of path through n to goal

 $\mathsf{A}^*$  search uses an admissible heuristic

i.e.,  $h(n) \le h^*(n)$  where  $h^*(n)$  is the **true** cost from n. (Also require  $h(n) \ge 0$ , so h(G) = 0 for any goal G.)

E.g.,  $h_{\mathrm{SLD}}(n)$  never overestimates the actual road distance

Theorem: A\* search is optimal

Chapter 4, Sections 1–2 16

## Properties of greedy search

Complete?? No-can get stuck in loops, e.g.,

 $\mathsf{lasi} \to \mathsf{Neamt} \to \mathsf{lasi} \to \mathsf{Neamt} \to$ 

Complete in finite space with repeated-state checking

<u>Time??</u>  $O(b^m)$ , but a good heuristic can give dramatic improvement

Space??  $O(b^m)$ —keeps all nodes in memory

Optimal??

### A\* search example

### Optimality of A\* (standard proof)

Suppose some suboptimal goal  $G_2$  has been generated and is in the queue. Let n be an unexpanded node on a shortest path to an optimal goal  $G_1$ .

 $f(G_2) = g(G_2)$  since  $h(G_2) = 0$ >  $g(G_1)$  since  $G_2$  is suboptimal  $\geq f(n)$  since h is admissible

Since  $f(G_2) > f(n)$ ,  $\mathbf{A}^*$  will never select  $G_2$  for expansion

Cluster ( Septem 1.0

#### A\* search example

#### Optimality of A\* (more useful)

Lemma:  $A^*$  expands nodes in order of increasing f value

Gradually adds "f-contours" of nodes (cf. breadth-first adds layers) Contour i has all nodes with  $f=f_i$ , where  $f_i < f_{i+1}$ 

Chapter 4, Sections 1-2 21 Chapter 4, Sections 1-2

### Properties of A\*

#### Complete??

## Properties of A\*

Complete?? Yes, unless there are infinitely many nodes with  $f \leq f(G)$ 

<u>Time</u>?? Exponential in [relative error in  $h \times$  length of soln.]

Space?? Keeps all nodes in memory

Optimal??

Chapter 4, Sections 1–2 25

Chapter 4 Sections 1-2

#### Properties of A<sup>\*</sup>

 $\underline{\text{Complete}??} \ \ \text{Yes, unless there are infinitely many nodes with} \ f \leq f(G)$   $\underline{\text{Time}??}$ 

#### Properties of A\*

 $\underline{\text{Complete}??} \text{ Yes, unless there are infinitely many nodes with } f \leq f(G)$ 

<u>Time??</u> Exponential in [relative error in  $h \times$  length of soln.]

Space?? Keeps all nodes in memory

Optimal?? Yes—cannot expand  $f_{i+1}$  until  $f_i$  is finished

 $\mathsf{A}^*$  expands all nodes with  $f(n) < C^*$ 

 $\mathsf{A}^*$  expands some nodes with  $f(n) = C^*$ 

 $\mathsf{A}^*$  expands no nodes with  $f(n) > C^*$ 

Chapter 4, Sections 1–2 26

Chapter 4, Sections 1–2 29

Complete?? Yes, unless there are infinitely many nodes with  $f \leq f(G)$ 

<u>Time</u>?? Exponential in [relative error in  $h \times$  length of soln.]

Space??

# Proof of lemma: Consistency

A heuristic is consistent if

$$h(n) \le c(n, a, n') + h(n')$$

If h is consistent, we have

$$\begin{split} f(n') &= g(n') + h(n') \\ &= g(n) + c(n, a, n') + h(n') \\ &\geq g(n) + h(n) \\ &= f(n) \end{split}$$

I.e., f(n) is nondecreasing along any path.

#### Admissible heuristics

E.g., for the 8-puzzle:

 $h_1(n) =$  number of misplaced tiles  $h_2(n) =$  total Manhattan distance

(i.e., no. of squares from desired location of each tile)

 $\frac{h_1(S) = ??}{h_2(S) = ??}$ 

Chapter 4, Sections 1–2 31

Chapter 4. Sections 1–2 32

#### Relaxed problems

Admissible heuristics can be derived from the **exact** solution cost of a **relaxed** version of the problem

If the rules of the 8-puzzle are relaxed so that a tile can move  ${\bf anywhere},$  then  $h_1(n)$  gives the shortest solution

If the rules are relaxed so that a tile can move to any adjacent square, then  $h_2(n)$  gives the shortest solution

Key point: the optimal solution cost of a relaxed problem is no greater than the optimal solution cost of the real problem

#### Admissible heuristics

E.g., for the 8-puzzle:

 $h_1(n) = \mathsf{number} \ \mathsf{of} \ \mathsf{misplaced} \ \mathsf{tiles}$ 

 $h_2(n)={\sf total}$  Manhattan distance

(i.e., no. of squares from desired location of each tile)

 $\underline{h_1(S)} = ?? 6$  $\underline{h_2(S)} = ?? 4+0+3+3+1+0+2+1 = 14$  Relaxed problems contd.

Well-known example: travelling salesperson problem (TSP) Find the shortest tour visiting all cities exactly once

Minimum spanning tree can be computed in  $O(n^2)$  and is a lower bound on the shortest (open) tour

Chapter 4, Sections 1–2

#### Dominance

If  $h_2(n) \geq h_1(n)$  for all n (both admissible) then  $h_2$  dominates  $h_1$  and is better for search

Typical search costs:

$$d=14 \ \ \mathsf{IDS} = \mathsf{3,473,941} \ \mathsf{nodes}$$
 
$$\mathsf{A}^*(h_1) = \mathsf{539} \ \mathsf{nodes}$$

$$A^*(h_2) = 113 \text{ nodes}$$

$$d = 24 \;\; \text{IDS} \approx 54,000,000,000 \; \text{nodes}$$
 
$$\mathsf{A}^*(h_1) = 39,135 \; \text{nodes}$$
 
$$\mathsf{A}^*(h_2) = 1,641 \; \text{nodes}$$

Given any admissible heuristics 
$$h_a$$
,  $h_b$ ,

$$h(n) = \max(h_a(n), h_b(n))$$

is also admissible and dominates  $h_a$ ,  $h_b$ 

#### Summary

Heuristic functions estimate costs of shortest paths

Good heuristics can dramatically reduce search cost

Greedy best-first search expands lowest  $\boldsymbol{h}$ 

- incomplete and not always optimal

 $\mathsf{A}^*$  search expands lowest g+h

- complete and optimal
- also optimally efficient (up to tie-breaks, for forward search)

Admissible heuristics can be derived from exact solution of relaxed problems
